Rate of mRNA Synthesis Transcription and Translation Linear Model for Rate of mRNA Synthesis Quadratic Function of Least Squares Best Fit

#### **Translation** of a bacterial mRNA

Joseph M. Mahaffy, (mahaffy@math.sdsu.edu)

**Definitions and Properties of Functions** 

- Begins shortly after transcription starts, with ribosomes reading the triplet codons on the mRNA
- Ribosome assembles a series of specific amino acids, forming a polypeptide
- Polypeptide probably folds passively into a tertiary structure which often combines with other proteins to become active or an enzyme

Translation

Rate of mRNA Synthesis **Transcription and Translation** Linear Model for Rate of mRNA Synthesis Quadratic Function of Least Squares Best Fit

#### Rate of mRNA Synthesis

#### Rate of mRNA Synthesis

- The rate of growth of a bacterial cell depends on the rate at which it assembles all of its cellular components inside the cell
- The rate of production of different components inside the cell varies depending on the length of time it takes for a cell to double
- The table below shows the doublings/hr,  $\mu$ , and the rate of mRNA synthesis (nucleotides/min/cell),  $r_m \times 10^5$

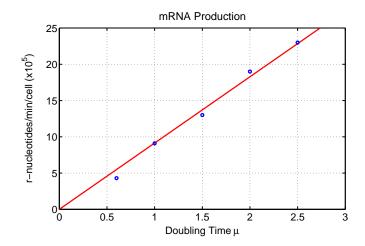

**SDS**(6/29)

 $\mathbf{2}$ 

SDSU

#### Least Squares Best Fit to Linear Model

Linear model passing through the origin has the form

 $r_m = a\mu$ 

- The linear least squares best fit of this model to the data uses only the slope of the model, *a*
- The sum of the squares of the errors is computed from each of the error terms

$$e_1^2 = (4.3 - 0.6a)^2$$
  

$$e_2^2 = (9.1 - a)^2$$
  

$$e_3^2 = (13 - 1.5a)^2$$
  

$$e_4^2 = (19 - 2a)^2$$
  

$$e_5^2 = (23 - 2.5a)^2$$

Lecture Notes – Function Review — (9/29)

SDSU

### Graph of Least Squares Function J(a)

**Graph of Least Squares Function** – Least Squares Best fit when a is at a minimum, the vertex  $a_v = 9.14$ 

#### Least Squares Best Fit to Linear Model

Sum of Square Errors is given by

$$J(a) = \sum_{i=1}^{5} e_i^2$$

which reduces to

$$J(a) = 13.86 a^2 - 253.36 a + 1160.3$$

- J(a) is a **quadratic function** representing the sum of the squares of the errors
- The best fit of the model is the smallest value of J(a)
- This occurs the vertex,  $a_v$ , of this quadratic equation

Function Review Definitions and Properties of Functions Vertical Line Test Function Operations Composition of Functions Even and Odd Functions One-to-One Functions Inverse Functions

### **Definitions and Properties of Functions**

#### **Definitions and Properties of Functions**

- Functions form the basis for most of this course
- A function is a relationship between one set of objects and another set of objects with only one possible association in the second set for each member of the first set

(12/29)

Definition of a Function Vertical Line Test Function Operations Composition of Functions Even and Odd Functions One-to-One Functions Inverse Functions

#### Rate of mNA Synthesis Example

#### mRNA Example has two functions

- A set of possible cell doubling times,  $\mu$ , to which was found a particular average rate of mRNA synthesis,  $r_m$
- This subdivides into two functional representations
  - The experimental data, which represents a function with a finite set of points
  - The linear model, which creates a different function representing your theoretical expectations
- The sum of the squares of the errors between the data points and the model, J(a), forms another function, where the set of possible slopes, a, in the model, each produced a number, J(a), representing how far away the model was from the true data
  - Claim that the best model is when this function is at its lowest point

## Definition of a Function

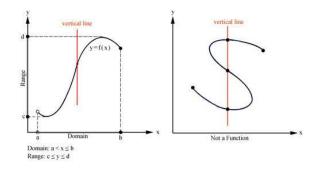

**Definition:** A function of a variable x is a rule f that assigns to each value of x a unique number f(x). The variable x is the **independent variable**, and the set of values over which x may vary is called the **domain** of the function. The set of values f(x) over the domain gives the **range** of the function

#### SDSU

#### Vertical Line Test

The **Vertical Line Test** states that a curve in the *xy*-plane is the graph of a function if and only if each vertical line touches the curve *at no more than one point* 

**Definition:** The graph of a function is defined by the set of points (x, y) such that y = f(x), where f is a function.

- Often a function is described by a **graph** in the *xy*-coordinate system
- By convention x is the domain of the function and y is the range of the function
- The **graph** is defined by the set of points (x, f(x)) for all x in the domain

5050

SDSU

Vertical Line Test **Function Operations Composition of Functions Inverse Functions** 

#### Example of Domain and Range

**Example 1:** Consider the function

 $f(t) = t^2 - 1$ 

Skip Example

a. What is the range of f(t) (assuming a domain of all t)?

**Solution a:** f(t) is a parabola with its vertex at (0, -1)pointing up.

Since the vertex is the low point of the function, it follows that range of f(t) is  $-1 \le y \le \infty$ 

**Example 1 (cont):** More on the function

$$f(t) = t^2 - 1$$

b. Find the domain of f(t), if the range of f is restricted to f(t) < 0

**Solution b:** Solving f(t) = 0 gives  $t = \pm 1$ 

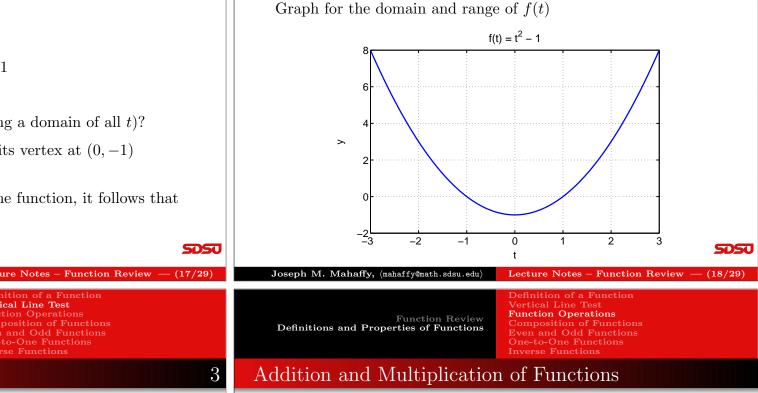

It follows that the domain is -1 < t < 1

Graph of Example 1

Vertical Line Test **Function Operations Composition of Functions** Even and Odd Functions **Inverse Functions** 

**Definitions and Properties of Functions** 

**Function Review** 

**Example 2:** Let f(x) = x - 1 and  $q(x) = x^2 + 2x - 3$ Skip Example

Determine f(x) + g(x) and f(x)g(x)**Solution:** The addition of the two functions

$$f(x) + g(x) = x - 1 + x^{2} + 2x - 3 = x^{2} + 3x - 4$$

The multiplication of the two functions

$$f(x)g(x) = (x-1)(x^2 + 2x - 3)$$
  
=  $x^3 + 2x^2 - 3x - x^2 - 2x + 3$   
=  $x^3 + x^2 - 5x + 3$ 

Definition of a Function Vertical Line Test **Function Operations** Composition of Functions Even and Odd Functions **Inverse Functions** 

#### Addition of Function

**Example 3:** Let

$$f(x) = \frac{3}{x-6}$$
 and  $g(x) = -\frac{2}{x+2}$ 

Skip Example

Determine f(x) + g(x)

**Solution:** The addition of the two functions

**Definitions and Properties of Functions** 

## **Composition** of Functions

**Example 4:** Let

$$f(x) = 3x + 2$$
 and  $g(x) = x^2 - 2x + 3$ 

Determine f(q(x))and g(f(x))

**Solution:** For the first composite function

$$f(g(x)) = 3(x^2 - 2x + 3) + 2 = 3x^2 - 6x + 11$$

The second composite function

$$g(f(x)) = (3x+2)^2 - 2(3x+2) + 3 = 9x^2 + 6x + 3$$

Clearly,  $f(g(x)) \neq g(f(x))$ 

**Function Review Definitions and Properties of Functions** 

Definition of a Function Vertical Line Test **Function Operations Composition of Functions Inverse Functions** 

## Composition of Functions

**Composition of Functions** is another important operation for functions

Given functions f(x) and q(x), the composite f(q(x)) is formed by inserting g(x) wherever x appears in f(x)

Note that the domain of the composite function is the range of g(x)

#### $\textbf{Joseph M. Mahaffy}, \ \langle \texttt{mahaffy}\texttt{@math.sdsu.edu} \rangle$ Lecture Notes – Function Review — (22/29)Vertical Line Test Function Review **Composition of Functions Definitions and Properties of Functions** Even and Odd Functions **One-to-One Functions** Even and Odd Functions

A function f is called:

SDSU

(23/29)

(21/29)

1. Even if f(x) = f(-x) for all x in the domain of f. In this case, the graph is symmetrical with respect to the y-axis

2. Odd if f(x) = -f(-x) for all x in the domain of f. In this case, the graph is symmetrical with respect to the origin

5051

Definition of a Function Vertical Line Test Function Operations Composition of Functions **Even and Odd Functions** One-to-One Functions Inverse Functions

#### Example of Even Function

Consider our previous example

 $f(t) = t^2 - 1$ 

Since

$$f(-t) = (-t)^2 - 1 = t^2 - 1 = f(t),$$

this is an even function.

The Graph of an Even Function is symmetric about the y-axis

**Inverse Functions** 

Definition of a Function Function Review Definitions and Properties of Functions Even and Odd Functions

 $\textbf{Joseph M. Mahaffy}, \; \langle \texttt{mahaffy}\texttt{@math.sdsu.edu} \rangle \\$ 

#### **Inverse Functions**

**Definition:** If a function f is **one-to-one**, then its corresponding **inverse function**, denoted  $f^{-1}$ , satisfies:

 $f(f^{-1}(x)) = x$  and  $f^{-1}(f(x)) = x$ .

Since these are composite functions, the domains of f and  $f^{-1}$  are restricted to the ranges of  $f^{-1}$  and f(x), respectively

Function Review Definitions and Properties of Functions Definition of a Function Vertical Line Test Function Operations Composition of Functions Even and Odd Functions **One-to-One Functions** Inverse Functions

SDSU

#### **One-to-One Function**

**Definition:** A function f is **one-to-one** if whenever  $x_1 \neq x_2$  in the domain, then  $f(x_1) \neq f(x_2)$ .

Equivalently, if  $f(x_1) = f(x_2)$ , then  $x_1 = x_2$ .

Function Review Definitions and Properties of Functions	Definition of a Function Vertical Line Test Function Operations Composition of Functions Even and Odd Functions One-to-One Functions Inverse Functions	
Example of an Inverse Function		

Consider the function

$$f(x) = x^3$$

It has the inverse function

$$f^{-1}(x) = x^{1/3}$$

The domain and range for these functions are all of x

$$f^{-1}(f(x)) = (x^3)^{1/3} = x = (x^{1/3})^3 = f(f^{-1}(x))$$
