**C Period for** *E. coli* Pulse Labeling Experiment Linear Model for C Period

# Cell Cycle in E. coli

#### Replication of DNA in E. coli

- Escherichia coli can divide every 20 minutes
- Time for the DNA to replicate is the C period
- Time for the two loops of DNA to split apart, segregate, and form two new daughter cells is the D period
- The C period is 35-50 min, and the D period is over 25 min
- Replication cycle often longer than cell division time
- Up to 8 *oriCs* in a single *E. coli*

Least Squares Analysis Least Squares Best Fit Worked Example 1 Error Analysis Worked Example 2

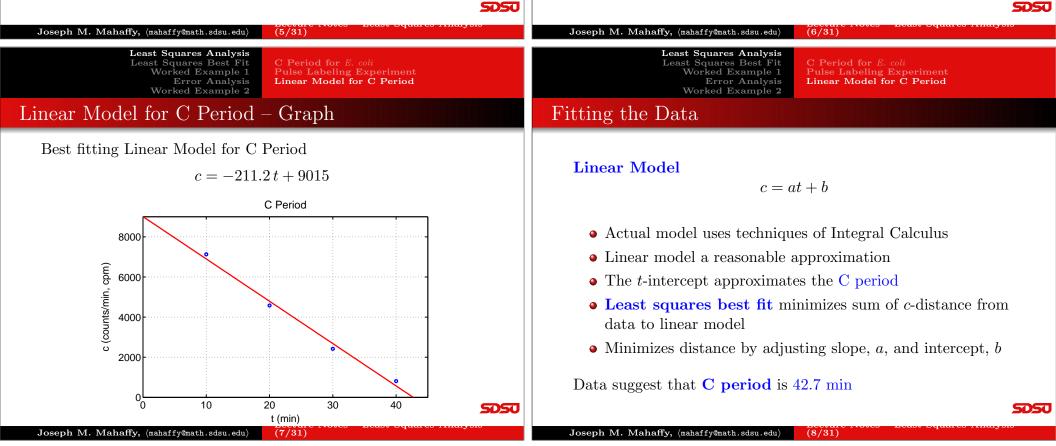

C Period for *E. coli* **Pulse Labeling Experiment** Linear Model for C Period

# Pulse Labeling Experiment

#### Finding the C Period

- A pulse of radioactive thymidine given to E. coli
- Drugs at t = 0 to stop new replication forks and division
- Radioactive thymidine added to existing forks
- As forks end, no new radioactive thymidine added
- Radioactive emissions, c in counts/min (cpm) measured in lab of Prof. Judith Zyskind (SDSU)

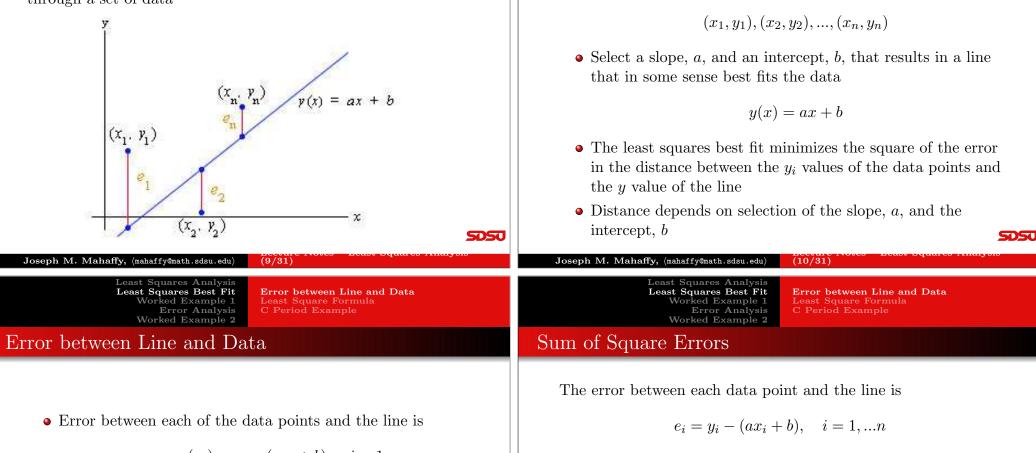

$t \pmod{t}$	10	20	30	40
c (cpm)	7130	4580	2420	810

Error between Line and Data Least Square Formula C Period Example

## Least Squares Best Fit

The **least squares best fit** of a line to data is the best line through a set of data

$$e_i = y_i - y(x_i) = y_i - (ax_i + b), \quad i = 1, ...n$$

• Define the **Absolute Error** between each of the data points and the line as

$$|e_i| = |y_i - y(x_i)| = |y_i - (ax_i + b)|, \quad i = 1, ..., n$$

• The error  $e_i$  varies as a and b vary

Least Squares Analysis Least Squares Best Fit Worked Example 1 Error Analysis Worked Example 2

Error between Line and Data Least Square Formula C Period Example

# Fitting the Data

• Consider a set of n data points:

Create a function depending on the slope a and intercept b of the line, which sums the square errors

$$J(a,b) = e_1^2 + e_2^2 + \ldots + e_n^2 = \sum_{i=1}^n e_i^2$$

The Least Squares Best Fit Line is the minimum value of the function J(a, b)

Minimum is determined using Calculus of two variables

Error between Line and I Least Square Formula C Period Example

#### Formula for Best Fitting Line

Assume data points  $(x_i, y_i), i = 1, ..., n$ , and line

y = ax + b

Define the mean of the x values

$$\bar{x} = \frac{x_1 + x_2 + \dots + x_n}{n} = \frac{1}{n} \sum_{i=1}^n x_i$$

The best fitting slope satisfies

$$a = \frac{\sum_{i=1}^{n} (x_i - \bar{x}) y_i}{\sum_{i=1}^{n} (x_i - \bar{x})^2}$$

The best fitting intercept satisfies

Joseph M. Mahaffy, (mahaffy@math.sdsu.edu)

$$b = \frac{1}{n} \sum_{i=1}^{n} y_i - a\bar{x} = \bar{y} - a\bar{x}$$

(13/31)

Error between Line and Data

C Period Example

Least Squares Analysis Least Squares Best Fit Worked Example 1 Error Analysis Worked Example 2

# C Period Example (continued)

Similarly, the c-intercept, b, satisfies:

$$b = \frac{7130 + 4580 + 2420 + 810}{4} - (-211.2)25$$
  

$$b = 9015$$

Thus, the best fitting line is given by

$$c(t) = -211.2t + 9015$$

Least Squares Analysis Least Squares Best Fit Worked Example 1 Error Analysis Worked Example 2

Error between Line and Data Least Square Formula C Period Example

# C Period Example (continued)

The pulse labeling experiment for *E. coli* gave data points:

$$(10, 7130), (20, 4580), (30, 2420), (40, 810)$$

The mean time is

 $\bar{t} = \frac{10 + 20 + 30 + 40}{4} = 25$ 

The best slope, a, satisfies

$$a = \frac{(10-25)7130+(20-25)4580+(30-25)2420+(40-25)810}{(10-25)^2+(20-25)^2+(30-25)^2+(40-25)^2}$$

$$a = -211.2$$

Error between Line and Data Least Square Formula C Period Example

### C Period Example - Error

With c(t) = -211.2t + 9015, compute the errors

For the first datum point (t, c) = (10, 7130), the model predicts c(10) = 6900, so

$$e_1 = c_1 - c(10) = 7130 - 6903 = 227$$

$$e_{2} = c_{2} - c(20) = 4580 - 4791 = -211$$
  

$$e_{3} = c_{3} - c(30) = 2420 - 2679 = -259$$
  

$$e_{4} = c_{4} - c(40) = 810 - 567 = 243$$

The sum of the square of these errors is

$$J(-211.2,9015) = 51529 + 44521 + 67081 + 59049 = 222180$$

# Juvenile Growth Model - Revisited

The linear Models section showed that Juvenile Height was approximated well with a linear model

Linear model is given by:

$$h(a) = 6.46 \, a + 72.3$$

and fit the data well

Least sum of square errors is found to be

$$J(m,b) = 41.5$$

# Applet for Juvenile Height Growth

Juvenile Growth Model - Revisited Two Research Models

## Example 1 - Model Choice

Two researchers had only a limited set of data, the points (2,2), (5,6), and (8,3).

Researcher A felt that the model given by with y increasing with increasing x

 $y = \frac{5}{9}x + \frac{8}{9}$ 

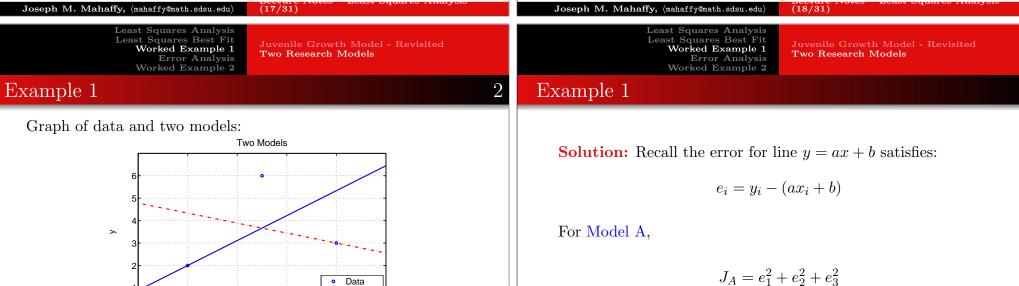

Researcher B felt that the model given by with y decreasing with increasing x

 $y = -\frac{2}{9}x + \frac{43}{9}$

# Example 1

4

#### What is the best fitting Linear model for these data?

**Solution:** The average x is

$$\bar{x} = \frac{2+5+8}{3} = 5$$

Best slope a satisfies:

$$a = \frac{(2-5)2+(5-5)6+(8-5)3}{(2-5)^2+(5-5)^2+(8-5)^2} = \frac{1}{6}$$

Since  $\bar{y} = \frac{11}{3}$ , the intercept *b* is

$$b = \bar{y} - a\bar{x} = \frac{11}{3} - \frac{5}{6} = \frac{17}{6}$$

The best linear model is

$$y = \frac{1}{6}x + \frac{17}{6}$$

SDSU

Percent and Relative Error

# **Relative and Percent Error**

- Relative and Percent error allow a better comparison of the error between data sets or within a data set with large differences in the numerical values
- Again let  $X_e$  be an experimental measurement or the worst value from a model being tested and  $X_t$  be a theoretical value or the best value from actual data
- The **Relative Error** is

$$\mathbf{Relative \ Error} = \frac{X_e - X_t}{X_t}$$

• The **Absolute Error** is appropriate when only the magnitude of the error is needed

**Percent Error** = 
$$\frac{X_e - X_t}{X_t} \times 100\%$$

### Growth Model

Consider the growth of a fish given by the data:

t (weeks)	0	1	2	3	5	7	9
L (cm)	2.4	3.1	3.7	4.1	5.2	4.9	6.9

**Growth Model** 

The formula for finding the least squares best fit linear model gives:

$$L = 0.437 t + 2.644$$

#### Determine the growth rate for this model

Solution: The rate of growth is the slope of the best fitting line, so

Growth Rate = 0.437 cm/week

SDSU

**Growth Model** 

# Growth Model

#### Which point is most likely erroneous?

The point with the most error is (7, 4.9)

When this point is removed, the new least squares best fit model is

L = 0.492t + 2.594

#### Determine the growth rate for this model

Growth Rate = 0.492 cm/week

Joseph M. Mahaffy, (mahaffy@math.sdsu.edu)

What is the new sum of square errors

**Solution:** The new sum of square errors is

J(a,b) = 0.0376 + 0.0002 + 0.0149 + 0.0009 + 0.0213 + 0.0149 = 0.0898

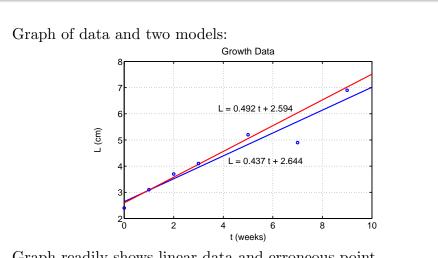

(29/31)

## Growth Model

4

SDSU

6

5050

#### What is the percent error between the computed growth rates?

Solution: The growth rate without the erroneous point is the best value, so

$$X_t = 0.492$$

The original growth rate is the worst value, so

 $X_e = 0.437$ 

Percent error is

 $\left(\frac{0.437 - 0.492}{0.492}\right) \times 100 = -11.2\%$
