We'll use t = 0 as 1790

Malthusian Growth Model

The most basic population model is the Malthusian growth model,

 $P(t) = P_0 e^{rt}$

We want the *least squares best fit* to the data:

Nelder-Mead Method

$$P_0 e^{rt_i} = P_i, \quad i = 0, \dots, m,$$

which with **natural logarithms** this becomes a **linear model**:

$$\ln P_0 + rt_i = a_0 + a_1 t_i = \ln P_i.$$

A *linear least squares fit* to this problem gives the coefficients (a_0, a_1) , where

$$P_0 = e^{a_0} \qquad \text{and} \qquad r = a_1$$

SDSU

SDSU

Malthusian Growth Sum of Square Errors Finding a Minimum

Malthusian Growth Model

From the U. S. population data and fitting the $\ln(P)$, we find

 $a_0 = 1.843853$ and $a_1 = 0.0196234$,

so the best fitting Malthusian growth model is

$$P(t) = 6.320851e^{0.0196234t}$$

The sum of square errors (SSE) for this model is

$$SSE = 48693.51.$$

This large error is largely caused by the bias of the logarithmic scale to over emphasize the early points.

Malthusian Growth **Sum of Square Errors** Finding a Minimum

Sum of Square Errors

The *sum of square errors* function is given by

```
1 function LS = mallstsqc(p0,r,t,y)
2 %Least Squares sum of square errors to Malthusian ...
    growth model
3 LS = sum((p0*exp(r*t)-y).^2);
4 end
```

The contour plot shows a classic **banana-shaped** curve with a long stretched **minimum**

Graphically, the **minimum** is clearly far from the parameters found by the **linear fit** to the **logarithms** of the data

However, this graph shows the **sum of square errors** for the **nonlinear Malthusian growth model**

Review U. S. Population Model Newton's Method Nelder-Mead Method Malthusian Growth Sum of Square Errors Finding a Minimum SDSU

Nelder-Mead Simplex Method

Define the sum of square errors with the two parameters

$$E(P_0, r) = \sum_{i=0}^{n} (P_0 e^{rt_i} - P_i)^2$$

Least Squares lecture showed MatLab's fminsearch [p,err]=fminsearch(@mallstsq,p0,[],t,pop) giving the best model as

$$P(t) = 16.345612e^{0.0136284t},$$

• Nelder-Mead Simplex Method

- Requires a "good" initial guess
- Uses triangular simplexes
- Algorithm searches space with **three** function evaluations. (No derivatives!)
- Computes centroid, then improves one of the three points **SOSU**
- Details for a future class. Math 693A? Joseph M. Mahaffy, (jmahaffy@mail.sdsu.edu) (11/46)

Review U. S. Population Model Newton's Method Nelder-Mead Method Malthusian Growth Sum of Square Errors Finding a Minimum

Method of Steepest Descent

The sum of square errors satisfies

$$E(P_0, r) = \sum_{i=0}^{n} (P_0 e^{rt_i} - P_i)^2$$

is a function of **two** variables

Recall from Calculus that $-\nabla E(P_0, r)$ (opposite the **gradient**) gives the direction of **steepest descent**, perpendicular to the level curve contours

• Method of Steepest Descent

- Gradient gives the directional derivative
- Follow path opposite $(x_n = [P_0^{(n)}, r^{(n)}])$

$$x_{n+1} = x_n - \alpha \nabla E(x_n)$$

- Find α such that $E(x_{n+1})$ is much smaller than $E(x_n)$
- "Banana curves" are notoriously slow for this method

Joseph M. Mahaffy, (jmahaffy@mail.sdsu.edu) (10/46)

Review U. S. Population Model Newton's Method Nelder-Mead Method Minimization Problem Line Search Method Newton's Method or Algorithm Example Population Model

Minimum – Sum of Square Errors

The graph of the **sum of square errors** shows a distinct minimum

The function of **two variables** is

$$E(P_0, r) = \sum_{i=0}^{n} \left(P_0 e^{rt_i} - P_i \right)^2$$

From Calculus, a necessary condition for a minimum is

 $\nabla E(P_0, r) = \mathbf{\tilde{0}}$

Taking partial derivatives gives

$$\frac{\partial E}{\partial P_0} = 2\sum_{i=0}^n \left(P_0 e^{rt_i} - P_i\right) e^{rt_i}$$
$$\frac{\partial E}{\partial r} = 2\sum_{i=0}^n \left(P_0 e^{rt_i} - P_i\right) P_0 t_i e^{rt_i}$$

5D5U

505

Minimization Problem Line Search Method Newton's Method or Algorithm Example Population Model

Nonlinear Least Squares - Malthusian Growth

The minimum occurs when these partial derivatives are zero

This requires solving two nonlinear equations for the parameters, ${\cal P}_0$ and r

$$\sum_{i=0}^{n} (P_0 e^{rt_i} - P_i) e^{rt_i} = 0$$
$$\sum_{i=0}^{n} (P_0 e^{rt_i} - P_i) P_0 t_i e^{rt_i} = 0$$

Note that the first equation could be solved for P_0 easily

This could be substituted into the second equation, and the resulting nonlinear equation could be solved by Newton's method or one of our other routine for solving f(x) = 0

Review U. S. Population Model Newton's Method Nelder-Mead Method Minimization Problem Line Search Method Newton's Method or Algorithm Example Population Model

Minimization Problem

Consider a function $f : \mathbb{R}^n \to \mathbb{R}$

Our problem is to minimize $f(\tilde{\mathbf{x}})$

$$\min_{\mathbf{\tilde{x}}\in\mathbb{R}^n} f(\mathbf{\tilde{x}}),$$

where

- $f(\tilde{\mathbf{x}})$ is the objective function
- $\mathbf{\tilde{x}}$ is the vector of variables or parameters

In our example above, the function f is the *sum of square errors*, and the vector $\tilde{\mathbf{x}} = [P_0, r]$

Joseph M. Mahaffy, (jmahaffy@mail.sdsu.edu) (13/46)Joseph M. Mahaffy, (jmahaffy@mail.sdsu.edu) (14/46)Minimization Problem Minimization Problem Review U. S. Population Model Review U. S. Population Model Newton's Method Newton's Method Nelder-Mead Method Nelder-Mead Method **Population Model Population Model** Minimization Problem Local Minimum

If $f(\tilde{\mathbf{x}}) \in \mathbb{R}$ is **differentiable** we can recognize a **minimum** by looking at the first and second derivatives:

- The gradient: $\nabla f(\tilde{\mathbf{x}}) \in \mathbb{R}^n$
- The **Hessian**: $\nabla^2 f(\tilde{\mathbf{x}}) \in \mathbb{R}^{n \times n}$

Once again **Taylor's Theorem** (multi-dimensional) plays a key role

Theorem (First Order Necessary Condition)

If $\tilde{\mathbf{x}}^*$ is a local minimum and f is continuously differentiable in an open neighborhood of $\tilde{\mathbf{x}}^*$, then

 $\nabla f(\tilde{\mathbf{x}}^*) = \tilde{\mathbf{0}}.$

SDSU

Joseph M. Mahaffy, (jmahaffy@mail.sdsu.edu) (16/46)

SDSU

SDSU

Definition (Positive Definite Matrix)

An $n \times n$ matrix H is **positive definite** if and only if for all $\mathbf{\tilde{x}} \neq 0$,

$$\tilde{\mathbf{x}}^T H \tilde{\mathbf{x}} = \sum_{i=1}^n \sum_{j=1}^n h_{ij} x_i x_j > 0$$

Theorem (Second-Order Sufficient Conditions)

Suppose that $\nabla^2 f$ is **continuous** in an open neighborhood of $\tilde{\mathbf{x}}^*$ and that $\nabla f(\tilde{\mathbf{x}}^*) = \tilde{\mathbf{0}}$ and $\nabla^2 f(\tilde{\mathbf{x}}^*)$ is **positive definite**. Then $\tilde{\mathbf{x}}^*$ is a **strict local minimum** of f.

Note: This is similar in 1-D of the derivative equal to zero and the second derivative being positive for a *local minimum*

Minimization Problem

Minimization Problem

We generally do not have a global picture of $f(\tilde{\mathbf{x}})$, so we concentrate on the local problem

Relying on our techniques from Calculus and the theorems above, we seek to solve

 $\nabla f(\tilde{\mathbf{x}}) = \tilde{\mathbf{0}}.$

We will concentrate on the case where there is a *local minimum*, so the **Hessian** is *positive definite*. (Math 693A will go into much more detail.)

We limit our discussion here to **Newton's Method**, which is a **line** search technique

Review U. S. Population Model Newton's Method Nelder-Mead Method

Minimization Problem Line Search Method

Line Search Method

Line search methods reduce the *n*-dimensional *minimization* problem

$$\min_{\mathbf{\tilde{x}}\in\mathbb{R}^n} f(\mathbf{\tilde{x}}),$$

with the one-dimensional problem

$$\min_{\tilde{\mathbf{x}}\in\mathbb{R}^n} f(\tilde{\mathbf{x}}_k + \alpha \tilde{\mathbf{p}}_k),$$

where $\tilde{\mathbf{p}}_k$ is a chosen *search direction* and α is the factor for how far we search in that direction.

Choice of $\tilde{\mathbf{p}}_k$ is critical to the rate of progress toward the *local* minimum

The intuitive *steepest descent* actually gives a slow scheme

SDSU Joseph M. Mahaffy, (jmahaffy@mail.sdsu.edu) (17/46)Joseph M. Mahaffy, (jmahaffy@mail.sdsu.edu) (18/46)Minimization Problem Minimization Problem Review U. S. Population Model Line Search Method Review U. S. Population Model Line Search Method Newton's Method Newton's Method Nelder-Mead Method Nelder-Mead Method **Population Model** Taylor Theorem Newton Direction

The **fundamental** building block for our *minimization problem* is once again **Taylor's Theorem** in higher dimensions

Theorem (Taylor's Theorem)

For some $t \in (0, 1)$, we have

$$f(\tilde{\mathbf{x}} + \tilde{\mathbf{p}}) = f(\tilde{\mathbf{x}}) + \tilde{\mathbf{p}}^T \underbrace{\nabla f(\tilde{\mathbf{x}})}_{gradient} + \frac{1}{2} \tilde{\mathbf{p}}^T \underbrace{\left[\nabla^2 f(\tilde{\mathbf{x}} + t\tilde{\mathbf{p}})\right]}_{Hessian} \tilde{\mathbf{p}}.$$

The *local minimum* occurs when we find $\mathbf{\tilde{x}}^*$, such that $\nabla f(\mathbf{\tilde{x}}^*) = \mathbf{\tilde{0}}$ and $\nabla^2 f(\tilde{\mathbf{x}}^*)$ is positive definite

If f is sufficiently smooth and the Hessian is positive definite, we can select $\tilde{\mathbf{p}}_k$ to be the Newton direction.

The second order Taylor expansion gives:

$$f(\tilde{\mathbf{x}} + \tilde{\mathbf{p}}) \approx f(\tilde{\mathbf{x}}) + \tilde{\mathbf{p}}^T \nabla f(\tilde{\mathbf{x}}) + \frac{1}{2} \tilde{\mathbf{p}}^T \left[\nabla^2 f(\tilde{\mathbf{x}}) \right] \tilde{\mathbf{p}}$$

The minimum of the rhs is obtained by computing the derivative with respect to $\tilde{\mathbf{p}}$ and setting the result to zero, so

$$\nabla f(\tilde{\mathbf{x}}) + \left[\nabla^2 f(\tilde{\mathbf{x}})\right] \tilde{\mathbf{p}} = \tilde{\mathbf{0}},$$

which gives the **Newton direction**

$$\mathbf{\tilde{p}}^{N} = -\left[\nabla^{2} f(\mathbf{\tilde{x}})\right]^{-1} \nabla f(\mathbf{\tilde{x}})$$

SDS

Minimization Problem Newton's Method or Algorithm

Newton's Method or Algorithm

Given an initial $\tilde{\mathbf{x}}_0$, Newton's Method for finding a *minimum* for $f(\mathbf{\tilde{x}})$ is iteratively given by

$$\tilde{\mathbf{x}}_{n+1} = \tilde{\mathbf{x}}_n - \left[\nabla^2 f(\tilde{\mathbf{x}}_n)\right]^{-1} \nabla f(\tilde{\mathbf{x}}_n).$$

More generally, let $\tilde{\mathbf{g}}(\tilde{\mathbf{x}}) : \mathbb{R}^n \to \mathbb{R}^n$, then Newton's Method can be used to find a solution of

$$\tilde{\mathbf{g}}(\tilde{\mathbf{x}}) = \tilde{\mathbf{0}}$$
 given initial $\tilde{\mathbf{x}}_0$.

The Newton iteration scheme satisfies

$$\tilde{\mathbf{x}}_{n+1} = \tilde{\mathbf{x}}_n - J^{-1}(\tilde{\mathbf{x}}_n)\tilde{\mathbf{g}}(\tilde{\mathbf{x}}_n)$$

where $J(\tilde{\mathbf{x}})$ is the **Jacobian matrix** for $\tilde{\mathbf{g}}(\tilde{\mathbf{x}})$

Review U. S. Population Model Newton's Method Nelder-Mead Method

Minimization Problem Newton's Method or Algorithm

Newton's Method for \mathbb{R}^3

Consider
$$\tilde{\mathbf{g}}(\tilde{\mathbf{x}}) : \mathbb{R}^3 \to \mathbb{R}^3$$
, where

$$\tilde{\mathbf{g}}(\tilde{\mathbf{x}}) = \begin{pmatrix} g_1(\tilde{\mathbf{x}}) \\ g_2(\tilde{\mathbf{x}}) \\ g_3(\tilde{\mathbf{x}}) \end{pmatrix} \quad \text{and} \quad \tilde{\mathbf{x}} = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}$$

The **Jacobian matrix** is given by

$$J(\tilde{\mathbf{x}}) = \begin{pmatrix} \frac{\partial g_1(\tilde{\mathbf{x}})}{\partial x_1} & \frac{\partial g_1(\tilde{\mathbf{x}})}{\partial x_2} & \frac{\partial g_1(\tilde{\mathbf{x}})}{\partial x_3} \\ \frac{\partial g_2(\tilde{\mathbf{x}})}{\partial x_1} & \frac{\partial g_2(\tilde{\mathbf{x}})}{\partial x_2} & \frac{\partial g_2(\tilde{\mathbf{x}})}{\partial x_3} \\ \frac{\partial g_3(\tilde{\mathbf{x}})}{\partial x_1} & \frac{\partial g_3(\tilde{\mathbf{x}})}{\partial x_2} & \frac{\partial g_3(\tilde{\mathbf{x}})}{\partial x_3} \end{pmatrix}$$

Then given an initial $\tilde{\mathbf{x}}_0$, Newton's Method can be used to find an approximate solution of $\tilde{\mathbf{g}}(\tilde{\mathbf{x}}) = \tilde{\mathbf{0}}$, where

$$\tilde{\mathbf{x}}_{n+1} = \tilde{\mathbf{x}}_n - J^{-1}(\tilde{\mathbf{x}}_n)\tilde{\mathbf{g}}(\tilde{\mathbf{x}}_n)$$

SDSU

SDSU

Suppose we want to find the intersection of the 2D curves

$$x_1^2 + x_2^2 = 4$$
 and $x_1 x_2 = 1$

(This could be easily solved in 1D, then back substituted.)

We create a
$$\tilde{\mathbf{g}}(x_1, x_2)$$
 with $\tilde{\mathbf{g}}(x_1, x_2) = \tilde{\mathbf{0}}$

$$\tilde{\mathbf{g}}(x_1, x_2) = \begin{pmatrix} x_1^2 + x_2^2 - 4 \\ x_1 x_2 - 1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

The **Jacobian matrix** is given by

$$J(\tilde{\mathbf{x}}) = \begin{pmatrix} 2x_1 & 2x_2 \\ x_2 & x_1 \end{pmatrix} \quad \text{so} \quad J^{-1}(\tilde{\mathbf{x}}) = \begin{pmatrix} \frac{x_1}{2(x_1^2 - x_2^2)} & -\frac{x_2}{(x_1^2 - x_2^2)} \\ -\frac{x_2}{2(x_1^2 - x_2^2)} & \frac{x_1}{(x_1^2 - x_2^2)} \end{pmatrix}$$

Given an initial $\tilde{\mathbf{x}}_0$, Newton's Method satisfies

$$\tilde{\mathbf{x}}_{n+1} = \tilde{\mathbf{x}}_n - J^{-1}(\tilde{\mathbf{x}}_n)\tilde{\mathbf{g}}(\tilde{\mathbf{x}}_n)$$

Given an initial $\tilde{\mathbf{x}}_0$, a MatLab version of Newton's Method is

| 1 | <pre>function xn = newton2(x0,tol,N)</pre> |

This Table shows **Newton's method** converging quadratically

A number of times this semester, we have employed the MatLab minimization algorithm fminsearch.

This algorithm employs the **Nelder-Mead method**¹, which is a heuristic technique based on searching parameter space with *simplexes*.

- This simplex method finds a *local minimum* of a function of several variables.
- If f(x, y) is function of two variables, the pattern starts with an initial triangle.
- The largest vertex is rejected and replaced with another.
- The process generates a sequence of triangles with vertices having smaller functional values.
- The size of the triangles eventually reduces to where it is sufficiently close to the *local minimum*.

¹ Nelder, John A., R. Mead (1965). A simplex method for function minimization. Computer Journal 7: 308313

Example Population Model Population Model - fminsearch

Nelder-Mead Method

The Nelder-Mead algorithm is developed using a *simplex*, which is a generalized triangle in N dimensions, and it follows an effective and computationally compact scheme.

For clarity, the Nelder-Mead algorithm is shown for f(x, y), a function of two variables².

Let f(x, y) be a function to be minimized, and select an initial triangle with vertices, $V_i = (x_i, y_i), i = 1, 2, 3$.

Step 1: Evaluate $z_i = f(x_i, y_i)$ for i = 1, 2, 3 and reorder so $z_1 \le z_2 \le z_3$, where

 $\mathbf{B} = (x_1, y_1), \quad \mathbf{G} = (x_2, y_2), \quad \mathbf{W} = (x_3, y_3).$

B is the *best vertex*, **G** is the *good vertex*, and **W** is the *worst vertex*.

Review U. S. Population Model Newton's Method Nelder-Mead Method Example Population Model Population Model - fminsearch

Nelder-Mead Method

Step 4: Expansion: If the function is smaller at **R** than $f(\mathbf{B})$, then this may be the correct direction toward the minimum, so extend the line segment another distance d to a point **E**:

$$\mathbf{E} = \mathbf{R} + (\mathbf{R} - \mathbf{M}) = 2\mathbf{R} - \mathbf{M}.$$

If $f(\mathbf{E}) < f(\mathbf{R})$, then this is a better vertex than \mathbf{R} , so create the new simplex **BEG** by replacing \mathbf{W} with \mathbf{E} and return to **Step 1**.

Review U. S. Population Model Newton's Method Nelder-Mead Method Example Population Model Population Model - fminsearch

Nelder-Mead Method

Step 2: Find the midpoint (centroid in higher dimensions) of the Good Side:

$$\mathbf{M} = \frac{\mathbf{B} + \mathbf{G}}{2} = \left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2}\right).$$

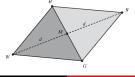

Step 3: Reflection: Create the line segment $\overline{\mathbf{MW}}$ through the midpoint with length *d*, then extend the line segment a distance *d* past **M** to find **R**, the *reflection point*:

$$\mathbf{R} = \mathbf{M} + (\mathbf{M} - \mathbf{W}) = 2\mathbf{M} - \mathbf{W}.$$

If the *reflected point* is better than the good vertex, \mathbf{G} , but not better than the good vertex, \mathbf{B} , so

 $f(\mathbf{B}) \le f(\mathbf{R}) < f(\mathbf{G}),$

then create the new simplex **BRG** by replacing W with R and return to **Step 1**.

Example Population Model Population Model - fminsearch

Nelder-Mead Method

Step 5: Contraction: If this stage is reached, then $f(\mathbf{R}) \ge f(\mathbf{G})$.

Find the midpoint of the line segment $\overline{\mathbf{MW}}$ and label this *contracted point* C.

If the contracted point is better than the worst point, $f(\mathbf{C}) < f(\mathbf{W})$, then this is a better vertex than \mathbf{W} , so create the new simplex **BCG** by replacing \mathbf{W} with \mathbf{C} and return to **Step 1**.

SDSC

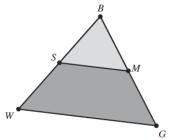

Example Population Model Population Model - fminsearch

Nelder-Mead Method

Step 6: **Shrink**: If this stage is reached (which rarely occurs), then none of the created points did better than **W**.

At this stage, the **best vertex**, **B** is kept and the simplex is shrunk.

In addition to finding \mathbf{M} , we find the midpoint, \mathbf{S} of the line segment $\overline{\mathbf{BW}}$, then create the new simplex **BMS** by replacing \mathbf{W} with \mathbf{S} and \mathbf{G} with \mathbf{M} and return to **Step 1**.

Nelder-Mead Method

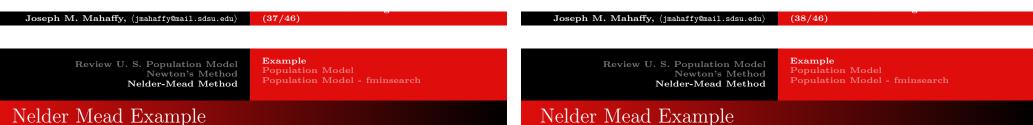

The *initial simplex* is important.

- If the initial simplex is too small, the solution can become trapped locally.
- The initial simplex often depends on the nature of the problem.

The *termination* conditions vary.

- The original paper of Nelder and Mead used the variation in the function values of the simplex.
- Alternately, one could compare the distance between the simplex nodes.
- The solution is taken as the last *best vertex* in the iteration.

SDSU

Consider the function:

$$f(x_1, x_2) = (x_1 - 3)^2 + (x_2 - 4)^2$$

- 1 function z = fcn(x) 2 %function here
- 3 $z=((x(1)-3)^2)+((x(2)-4)^2);$
- 4 end

This clearly has a *minimum* at $(x_1, x_2) = (3, 4)$.

The **Nelder-Mead Algorithm** is applied to this problem with initial simplexes:

V: (0,0), (1,0), (0,1)

2
$$V: (0,0), (6,0), (0,6)$$

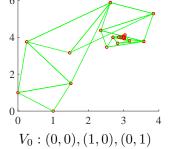

Iterations are seen on the next slide.

Fitting the Population Model with MatLab

Recall that the function we want to minimize is the **nonlinear sum** of square errors:

$$E(P_0, r) = \sum_{i=0}^{n} (P_0 e^{rt_i} - P_i)^2$$

In MatLab

1 function LS = mallstsq(p,t,y)
2 %Least Squares sum of square errors to Malthusian ...
 growth model
3 LS = sum((p(1)*exp(p(2)*t)-y).^2);
4 end

We apply the MatLab function fminsearch, using the multidimensional unconstrained nonlinear minimization (Nelder-Mead).

Joseph M. Mahaffy, (jmahaffy@mail.sdsu.edu) (45/46)

Review U. S. Population Model Newton's Method Nelder-Mead Method Example Population Model Population Model - fminsearch

Fitting the Population Model with MatLab

The output from the MatLab command [p, err] = fminsearch (@mallstsq, p0, [], t, pop)is p = [16.345612, 0.0136284] and err = 2875.53

This gives the Nonlinear Least Squares Best Model

$$P(t) = 16.345612e^{0.0136284t}$$

with a substantially improved sum of square error = 2875.53
